Galois representations attached to Drinfeld modules

都立大理 田口 雄一郎 (Yuichiro Taguchi)

In the talk, I announced some results on Galois representations attached to Drinfeld modules (see §1 below) and sketched the proof of the finiteness theorem (1.2). In this note, I will show how a theorem of Fontaine (Théorème 1 of [4]) can be modified (§3) so as to work in the course of the proof of Theorem (1.3).

1. Results and proofs

In this section, let K be an algebraic function field in one variable over a finite field. Fix once for all a place ∞ of K , and let A be the ring of elements of K which are regular outside ∞ .

Let F be a field of finite type over A , i.e., a field F which is endowed with a ring homomorphism $\gamma : A \rightarrow F$ and is finitely generated over $\text{Im}(\gamma)$ as a field. We say that the “characteristic” of F is *infinite* if γ is injective and *finite* if $\text{Ker}(\gamma)$ is a non-zero prime ideal \mathfrak{p} of A , and write “char”(F) = ∞ or \mathfrak{p} accordingly.

Given a Drinfeld module ϕ over F of rank r , one can attach the v -adic Tate module $T_v(\phi)$ for any non-zero prime ideal $v \neq \text{“char”}(F)$. This is a free A_v -module (A_v is the v -adic completion of A) of rank r on which the absolute Galois group $\text{Gal}(F^{\text{sep}}/F)$ acts continuously. For fundamentals of Drinfeld modules, see [1] and [2]. (See also [5] in this volume.)

Denote by K_v the fraction field of A_v . Our main result is:

THEOREM (1.1) ([6], [7]). Assume F is a finite extension of K or “char”(F) is finite. Let ϕ be a Drinfeld module over F . Then for any non-zero prime ideal v of A different from “char”(F), $T_v(\phi) \otimes_{A_v} K_v$ is a semi-simple $K_v[\text{Gal}(F^{\text{sep}}/F)]$ -module.

This follows ([6], Appendix) from

THEOREM (1.2) ([6], [7]). Let F , ϕ and v be as in (1.1). For any $\text{Gal}(F^{\text{sep}}/F)$ -stable A_v -direct summand of $T_v(\phi)$, to which corresponds a sequence $\phi \rightarrow \phi_1 \rightarrow \phi_2 \rightarrow \dots$ of isogenies of Drinfeld modules over F , there are only finitely many isomorphism classes of Drinfeld modules in $\{ \phi_n ; n \geq 1 \}$.

Remark. The assumption that the extension F/K is finite (when “char”(F) = ∞) should be removed, but I have not yet checked it.

The proof of (1.2) goes in a similar way as in Zarhin [8] and Faltings [3], and uses the theory of *modular heights*. In the infinite “characteristic” case, the Arakelov theoretic arguments and the study of π -divisible groups are needed. For details, see [6] and [7].

Now we restrict ourselves to the case where F is a finite extension of K . Then for a Drinfeld module ϕ over F , we can define the “discriminant” $\Delta(\phi)$ of ϕ ([7], §6), which is an ideal of the integral closure R of A in F .

THEOREM (1.3) ([7], §6). *Let \mathfrak{n} be a non-zero ideal of R and \mathfrak{v} a non-zero prime ideal of A . Then there are only finitely many isomorphism classes of Galois representations $T_{\mathfrak{v}}(\phi) \otimes_{A_{\mathfrak{v}}} K_{\mathfrak{v}}$ arising from Drinfeld modules ϕ over F with $\Delta(\phi)|\mathfrak{n}$.*

In the case of abelian varieties, the corresponding theorem ([3], Satz 5) holds under a weaker restriction (i.e. “ $\text{Supp}(\Delta(\phi)) \subset \text{Supp}(\mathfrak{n})$ ” replacing “ $\Delta(\phi)|\mathfrak{n}$ ”). But it is unlikely that we can weaken the restriction in our case because of the lack of the Hermite-Minkovski theorem for function fields. So the proof of our theorem requires an estimate of the differentials of field extensions arising from division points of Drinfeld modules:

PROPOSITION (1.4) ([7], §6). *Let ϕ be a Drinfeld module over F of rank r , and let $a \in A - 0$. Then we have the following inequality of divisors (denoted additively) of F :*

$$\mathfrak{D}(F(\phi; a)/F) \leq r \left[(a) + \delta(r, a) q^{r \deg(a) - 2} \Delta(\phi) + (q^r - 2) \cdot \infty \right],$$

where $F(\phi; a)$ is the field of a -division points of ϕ/F , $\mathfrak{D}(/)$ the different, q the cardinality of the constant field of K , $\deg(a) := \log_q \#(A/aA)$, and $\delta(r, a) := (q^{r \deg(a)} - 1)/(q - 1)$.

The estimate of the different is performed separately at each infinite or finite place of F . In the case of infinite places, a “successive minimum base” of an A -lattice is used ([7], (6.6)). The case of finite places is easy ([7], (6.4) and (6.5)), but it would be interesting to give a general statement (Theorem (3.4) below), which can be regarded as a higher dimensional generalization of (6.4) of [7].

2. The Taylor expansion

This section is a preliminary for §3.

Let R be a commutative ring and $R[[X]] = R[[X_1, \dots, X_h]]$ the ring of formal power series over R in h variables. For a multi-index $n = (n_1, \dots, n_h) \in \mathbb{N}^h$ (\mathbb{N} is the set of natural numbers including 0), we define a “differential operator” $\frac{\delta^n}{\delta X^n}$ as follows:

If $f(X) = \sum a_m X^m = \sum a_{m_1, \dots, m_h} X_1^{m_1} \dots X_h^{m_h} \in R[[X]]$, then

$$\begin{aligned} \frac{\delta^n}{\delta X^n} f(X) &:= \sum a_m \binom{m}{n} X^{m-n} \\ &= \sum a_{m_1, \dots, m_h} \binom{m_1}{n_1} \dots \binom{m_h}{n_h} X_1^{m_1-n_1} \dots X_h^{m_h-n_h}, \end{aligned}$$

where $\binom{m}{n} = \binom{m_1}{n_1} \dots \binom{m_h}{n_h}$ is the “multi-binomial coefficient” with $\binom{m_i}{n_i} := 0$ if $n_i > m_i$.

Remarks (2.1). (1) $\frac{\delta^n}{\delta X^n}$ is R -linear.

(2) $\frac{\partial^n}{\partial X^n} = n! \frac{\delta^n}{\delta X^n}$ (where $n! := n_1! \dots n_h!$) is the usual differential operator, and $\frac{\delta^n}{\delta X^n} = \frac{1}{n!} \left(\frac{\partial}{\partial X} \right)^n$ if $n!$ is invertible in R . In particular, we have $\frac{\partial}{\partial X} = \frac{\delta}{\delta X}$.

(3) For $f(X) \in R[[X]]$, put $f_Y(X) := f(X + Y) \in R[[X, Y]] = R[[X]][[Y]]$. We have

$$\frac{\delta^n}{\delta X^n} f_Y(X) = \left(\frac{\delta^n}{\delta X^n} f \right)(X + Y) \quad \text{in } R[[X, Y]].$$

$$(4) \quad \frac{\delta^n}{\delta X^n} (fg) = \sum_{k+l=n} \left(\frac{\delta^k}{\delta X^k} f \right) \left(\frac{\delta^l}{\delta X^l} g \right) \quad \text{for } f, g \in R[[X]].$$

(5) Let S be an R -algebra and I an ideal of S . Assume S is complete with respect to the I -adic topology. If $f(X) \in R[[X]]$ has the value $f(x) \in S$ at a point $x = (x_1, \dots, x_h) \in S^h$, then $\frac{\delta^n}{\delta X^n} f(X)$ also has the value $\frac{\delta^n}{\delta X^n} f(x)$ at x for any $n \in \mathbb{N}^h$.

PROPOSITION (2.2). For $f(X) \in R[[X]]$, we have the formal Taylor expansion (or rather, the binomial expansion)

$$(2.2.1) \quad f(X + Y) = \sum_{|n| \geq 0} \frac{\delta^n}{\delta X^n} f(X) \cdot Y^n \quad \text{in } R[[X, Y]].$$

If $f(X)$ has the value $f(x) \in S$ at $x \in S^h$ and y is an element of I^h , then $f(x+y) \in S$ also exists and we have

$$(2.2.2) \quad f(x+y) = \sum_{|n| \geq 0} \frac{\delta^n}{\delta X^n} f(x) \cdot y^n \quad \text{in } S.$$

Proof. Write $f(X+Y) = \sum a_n(X)Y^n$ with $a_n(X) \in R[[X]]$. Applying $\frac{\delta^n}{\delta X^n}$ to both sides and reducing modulo Y , we obtain (cf. Remark (2.1), (3))

$$\frac{\delta^n}{\delta Y^n} f(X) = a_n(X)$$

and hence (2.2.1).

The latter half of the Proposition is obvious.

3. Estimate of differentials

First we recall Fontaine's numbering of the ramification groups of a local field and some of his results ([4], §1). Throughout this section, if L is a discrete valuation field, \mathfrak{O}_L (resp. \mathfrak{m}_L , resp. k_L) denotes the integer ring of L (resp. the maximal ideal of \mathfrak{O}_L , resp. the residue field $\mathfrak{O}_L/\mathfrak{m}_L$).

In the following, K is a complete discrete valuation field with perfect residue field k of characteristic $p \neq 0$. Let v_K denote the valuation on K normalized by $v_K(K^\times) = \mathbb{Z}$, and also its unique extension to any algebraic extension of K . If \mathfrak{a} is a subset of an algebraic extension of K , we put $v_K(\mathfrak{a}) := \inf\{v_K(x); x \in \mathfrak{a}\}$.

For a finite Galois extension L/K , Fontaine defines a lower (resp. upper) filtration $G_{(i)}$ (resp. $G^{(u)}$) ($i, u \in \mathbb{R}$) on the Galois group $G = \text{Gal}(L/K)$, which is connected with the usual filtration G_i (resp. G^u) defined in Chapitre IV of [Corps locaux] by

$$G_i = G_{((i+1)/e)}, \quad \text{resp.} \quad G^u = G^{(u+1)},$$

where $e = e_{L/K}$ is the ramification index of L/K .

He also defines a real number $i_{L/K}$ (resp. $u_{L/K}$), which is characterized as the largest real number i (resp. u) such that $G_{(i)} \neq 1$ (resp. $G^{(u)} \neq 1$). $i_{L/K}$ and $u_{L/K}$ are connected by

$$u_{L/K} = \int_0^{i_{L/K}} (G_{(x)} : 1) dx.$$

Then he proves the following

PROPOSITION (3.1). Let L be a finite Galois extension of K .

(1) ([4], 1.3) Let $\mathfrak{D}_{L/K}$ be the different of the extension L/K . We have

$$v_K(\mathfrak{D}_{L/K}) = u_{L/K} - i_{L/K}.$$

(2) ([4], 1.5) For a real number $m \geq 0$, consider the following property (P_m) on the extension L/K :

$$(P_m) \left\{ \begin{array}{l} \text{For any algebraic extension } E \text{ of } K, \text{ if there exists} \\ \text{an } \mathfrak{D}_K\text{-algebra homomorphism : } \mathfrak{D}_L \rightarrow \mathfrak{D}_E/\mathfrak{a}_{E/K}^m \\ \text{(where } \mathfrak{a}_{E/K}^m := \{x \in \mathfrak{D}_E; v_K(x) \geq m\} \text{),} \\ \text{then there exists a } K\text{-embedding : } L \hookrightarrow E. \end{array} \right.$$

Then

- (i) if $m > u_{L/K}$, L/K has the property (P_m) ;
- (ii) if L/K has the property (P_m) , we have $m > u_{L/K} - e_{L/K}^{-1}$.

Now we shall refine Fontaine's Proposition 1.7 of [4] as follows. The main point is that it works, *mutatis mutandis*, even in positive characteristics.

PROPOSITION (3.2). Let B be a finite flat \mathfrak{D}_K -algebra which is locally of complete intersection over \mathfrak{D}_K . Suppose that there exists an element $a \in \mathfrak{D}_K$ such that $\Omega_{B/\mathfrak{D}_K}^1$ is a flat (B/aB) -module.

(i) Let S be a finite flat \mathfrak{D}_K -algebra and I an ideal of S . Suppose either the S -submodule $a^{-1}I^{p-1}$ of $K \otimes_{\mathfrak{D}_K} S$ is topologically nilpotent (i.e. $\cap_{n \geq 1} (a^{-1}I^{p-1})^n = 0$), or I has a PD-structure such that $\cap_{n \geq 1} I^{[n]} = 0$.

(a) For any \mathfrak{D}_K -algebra homomorphism $u : B \rightarrow S/aI$, there exists an \mathfrak{D}_K -algebra homomorphism $\hat{u} : B \rightarrow S$ which is uniquely determined by $u(\text{mod.} I)$ and makes the following diagram commutative:

$$\begin{array}{ccc} B & \xrightarrow{u} & S/aI \\ \hat{u} \downarrow & & \downarrow \\ S & \longrightarrow & S/I. \end{array}$$

(b) The canonical map of sets

$$\text{Hom}_{\mathfrak{D}_K\text{-alg}}(B, S) \longrightarrow \text{Hom}_{\mathfrak{D}_K\text{-alg}}(B, S/I)$$

is injective.

(ii) The K -algebra $B_K := K \otimes_{\mathcal{O}_K} B$ is étale. Let L be the smallest subfield of a separable closure K^{sep} of K which contains the images $u(B)$ for all $u \in \text{Hom}_{K-\text{alg}}(B_K, K^{sep})$. Then L/K is a finite Galois extension and $u_{L/K} \leq v_K(a) + \frac{1}{p-1} \cdot \min\{v_K(a), v_K(p)\}$.

The proof is essentially the same as the original one due to Fontaine, but we reproduce his proof here for the convenience of the reader.

Proof. (i),(a): We may and do suppose B is a local ring, because B is the product of a finite number of local rings. Let \mathfrak{m}_B be the maximal ideal of B . Replacing K by an unramified extension if necessary, we may also suppose $B/\mathfrak{m}_B = k$, the residue field of \mathcal{O}_K .

Then $\Omega_{B/\mathcal{O}_K}^1$ is a free (B/aB) -module. Let x_1, \dots, x_h be elements of \mathfrak{m}_B the images of which form a k -base of $\mathfrak{m}_B/(\mathfrak{m}_B^2 + \mathfrak{m}_K B)$. We see from the definition of differential modules that dx_1, \dots, dx_h generate $\Omega_{B/\mathcal{O}_K}^1$, and further, they form a (B/aB) -base of $\Omega_{B/\mathcal{O}_K}^1$ because of the canonical isomorphisms

$$\Omega_{B/\mathcal{O}_K}^1 \otimes_B B_o \xrightarrow{\sim} \Omega_{B_o/k}^1 \quad (B_o := B/\mathfrak{m}_K B),$$

$$\mathfrak{m}_B/(\mathfrak{m}_B^2 + \mathfrak{m}_K B) \xrightarrow{\sim} \mathfrak{m}_{B_o}/\mathfrak{m}_{B_o}^2 \xrightarrow{\sim} \Omega_{B_o/k}^1 \otimes_{B_o} k,$$

where $\mathfrak{m}_{B_o} = \mathfrak{m}_B/\mathfrak{m}_K B$ is the maximal ideal of B_o .

Now let

$$\alpha : \mathcal{O}_K[[X_1, \dots, X_h]] \longrightarrow B$$

be the unique continuous \mathcal{O}_K -algebra homomorphism such that $\alpha(X_j) = x_j$, and let $J := \text{Ker}(\alpha)$. Since B is finite of complete intersection over \mathcal{O}_K , J is generated by h elements, say $P_1, \dots, P_h \in \mathcal{O}_K[[X_1, \dots, X_h]]$.

For each i , we have $\sum_j \frac{\delta P_i}{\delta X_j}(x_1, \dots, x_h) dx_j = 0$ (note $\frac{\delta}{\delta X_j} = \frac{\partial}{\partial X_j}$), which implies $\frac{\delta P_i}{\delta X_j}(x_1, \dots, x_h) \in aB$. Hence there are $p_{ij} \in B$ such that $\frac{\delta P_i}{\delta X_j}(x_1, \dots, x_h) = ap_{ij}$. The fact that $\Omega_{B/\mathcal{O}_K}^1$ is a free (B/aB) -module means that the free B -submodule of $\oplus_{j=1}^h B dX_j$ generated by $\sum_j \frac{\delta P_i}{\delta X_j}(x_1, \dots, x_h) dX_j$, $1 \leq i \leq h$, coincides with the one generated by adX_j , $1 \leq j \leq h$. We can therefore find $q_{li} \in B$ such that

$$adX_l = \sum_i q_{li} \left(\sum_j \frac{\delta P_i}{\delta X_j}(x_1, \dots, x_h) dX_j \right), \quad 1 \leq l \leq h,$$

i.e., $a1_h = (q_{li})(ap_{ij})$. (1_h is the unit matrix of degree h .) Since B is a free \mathcal{O}_K -module, we can divide both sides by a . Thus the matrix (p_{ij}) is invertible in $M_h(B)$ and $(q_{li}) = (p_{ij})^{-1}$.

The case of PD-ideals is proved in [4], so we suppose $a^{-1}I^{p-1}$ is topologically nilpotent. Then the ideal $a^{-1}I^{p-1} + I$ is also topologically nilpotent. Set $I_n := (a^{-1}I^{p-1} + I)^{n-1}I$, $n \geq 1$ (so that $a^{-1}I_n^{p-1}$ is again topologically nilpotent, and S is canonically isomorphic to the projective limit of the system $(S/I_n)_{n \geq 1}$). It is easily seen that $I_n^p \subset aI_{2n}$ and $I_n^2 \subset I_{2n}$. To show the assertion, it is enough to verify:

For any integer $n \geq 1$ and an \mathfrak{O}_K -algebra homomorphism $u : B \rightarrow S/aI_n$, there exists an \mathfrak{O}_K -algebra homomorphism $u' : B \rightarrow S/aI_{2n}$ such that $u'(\text{mod. } I_{2n})$ is uniquely determined by $u(\text{mod. } I_n)$ and u' makes the following diagram commutative:

$$\begin{array}{ccc} B & \xrightarrow{u} & S/aI_n \\ u' \downarrow & & \downarrow \\ S/aI_{2n} & \longrightarrow & S/I_n. \end{array}$$

In other words, writing I for I_n and I_2 for I_{2n} :

For any elements u_1, \dots, u_h of S such that

$$P_i(u_1, \dots, u_h) = a\lambda_i \quad \text{with some } \lambda_i \in I \quad (1 \leq i \leq h),$$

there exist $\mu_1, \dots, \mu_h \in I$ such that $\mu_j(\text{mod. } I_2)$ are uniquely determined by $u_j(\text{mod. } I)$ and

$$(3.2.1) \quad P_i(u_1 + \mu_1, \dots, u_h + \mu_h) \in aI_2 \quad (1 \leq i \leq h).$$

If $\mu_j \in I$, we have the Taylor expansion (2.2.2)

$$(3.2.2) \quad P_i(u_1 + \mu_1, \dots, u_h + \mu_h) = a\lambda_i + \sum_j \frac{\delta P_i}{\delta X_j}(u_1, \dots, u_h)\mu_j + R_i$$

with $R_i := \sum_{|\mathbf{r}| \geq 2} \frac{\delta^{\mathbf{r}} P_i}{\delta X^{\mathbf{r}}}(u_1, \dots, u_h)$.

For any element $P \in J$, we have $\frac{\delta P}{\delta X_j}(x_1, \dots, x_h) \in aB$, i.e.

$$\frac{\delta P}{\delta X_j}(X_1, \dots, X_h) \in a\mathfrak{O}_K[[X_1, \dots, X_h]] + J.$$

If $|\mathbf{r}| \geq 1$ and $r!$ is invertible in \mathfrak{O}_K , we see inductively (cf. Remark (2.1), (2))

$$\frac{\delta^{\mathbf{r}} P}{\delta X^{\mathbf{r}}}(X_1, \dots, X_h) \in a\mathfrak{O}_K[[X_1, \dots, X_h]] + J,$$

so

$$\frac{\delta^r P}{\delta X^r}(u_1, \dots, u_h) \in aS + aI = aS.$$

Since $I^2 \subset I_2$, we have

$$\frac{\delta^r P}{\delta X^r}(u_1, \dots, u_h) \cdot \mu^r \in aI_2,$$

if $|r| \geq 2$ and $r!$ is invertible in \mathfrak{O}_K .

On the other hand, we have $\mu^r \in I^{|r|} \subset I^p \subset aI_2$ if p divides $r!$, and $\frac{\delta^r P}{\delta X^r}(u_1, \dots, u_h)$ are always in S (Remark (2.1), (5)). Thus we have

$$(3.2.3) \quad R_i \in aI_2.$$

Take an element $P_{ij} \in \mathfrak{O}_K[[X_1, \dots, X_h]]$ such that $\alpha(P_{ij}) = p_{ij} \in B$ for each (i, j) . We have

$$\frac{\delta P_i}{\delta X_j}(x_1, \dots, x_h) = ap_{ij},$$

i.e. $\frac{\delta P_i}{\delta X_j} = aP_{ij} + R_{ij}$ with some $R_{ij} \in J$, from which follows the congruence

$$\frac{\delta P_i}{\delta X_j}(u_1, \dots, u_h) \equiv aP_{ij}(u_1, \dots, u_h) \pmod{aI},$$

and

$$(3.2.4) \quad \frac{\delta P_i}{\delta X_j}(u_1, \dots, u_h) \cdot \mu_j \equiv aP_{ij}(u_1, \dots, u_h) \cdot \mu_j \pmod{aI_2}.$$

Putting (3.2.3) and (3.2.4) into (3.2.2), we have

$$P_i(u_1 + \mu_1, \dots, u_h + \mu_h) \equiv a(\lambda_i + \sum_j P_{ij}(u_1, \dots, u_h) \cdot \mu_j) \pmod{aI_2}.$$

Since S is flat over \mathfrak{O}_K , the condition (3.2.1) for μ_j is now equivalent to

$$\lambda_i + \sum_j P_{ij}(u_1, \dots, u_h) \cdot \mu_j \equiv 0 \pmod{I_2}, \quad 1 \leq i \leq h.$$

Since the matrix $(p_{ij}) = (P_{ij}(x_1, \dots, x_h))$ is invertible, the matrix $(P_{ij}(u_1, \dots, u_h))$ is invertible modulo aI . Now the existence of $\mu_j \in I$ satisfying (3.2.1) is clear. Moreover $u_j \pmod{I}$, $1 \leq j \leq h$, determine

$\mu_j(\text{mod. } I_2)$, $1 \leq j \leq h$, uniquely, because they determine $\lambda_i \equiv 0 \pmod{I}$ and $P_{ij}(u_1, \dots, u_h) \pmod{I}$ uniquely and $I^2 \subset I_2$.

Part (b) of (i) follows immediately from Part (a).

Proof of (ii): Since B_K is finite over K and $\Omega_{B_K/K}^1 = K \otimes_{\mathfrak{O}_K} \Omega_{B/\mathfrak{O}_K}^1 = 0$, B_K is étale over K . So we can write $B_K = \prod_{s=1}^t L_s$, where L_s are finite separable extensions of K assumed to be contained in K^{sep} , a fixed separable closure of K . Then L is the composition of the Galois closures in K^{sep} of L_s/K , $s = 1, \dots, t$. Hence L/K is a Galois extension.

If a is a unit, then $\Omega_{B/\mathfrak{O}_K}^1 = 0$, B is étale over \mathfrak{O}_K , L/K is unramified, and $u_{L/K} = 0$.

Suppose $a \in \mathfrak{m}_K$. We will show that L/K has the property (P_m) for any $m > v_K(a) + \varepsilon$ with $\varepsilon := \frac{1}{p-1} \cdot \min\{v_K(a), v_K(p)\}$.

Writing $J(E) := \text{Hom}_{\mathfrak{O}_K\text{-alg}}(B, \mathfrak{O}_E)$ for a finite extension E of K , we see that

$$\begin{aligned} J(E) &= \text{Hom}_{K\text{-alg}}(B_K, E) \\ &= \prod_{s=1}^t \{K\text{-embeddings } L_s \hookrightarrow E\}. \end{aligned}$$

Here we have $\#\{K\text{-embeddings } L_s \hookrightarrow E\} \leq [L_s : K]$ and the equality holds if and only if E contains a subfield which is K -isomorphic to the Galois closure of L_s/K in K^{sep} . Hence we have

$$\#J(E) \leq \#J(L)$$

and the equality holds if and only if there exists a K -embedding $L \hookrightarrow E$. So it suffices to show :

If there exists an \mathfrak{O}_K -algebra homomorphism

$$\eta : \mathfrak{O}_L \longrightarrow \mathfrak{O}_E / \mathfrak{a}_{E/K}^m \quad \text{with } m > v_K(a) + \varepsilon,$$

then we have $\#J(E) \leq \#J(L)$.

Noticing that $\mathfrak{a}_{E/K}^m$ is of the form aI with an ideal I of \mathfrak{O}_E which satisfies the assumption of Part (i), we can define, by (a) of (i), a map

$$J(L) \longrightarrow J(E) \quad ; \quad u \longmapsto u^\eta,$$

where u^η is the unique element of $J(E)$ which makes the following diagram commutative:

$$\begin{array}{ccc} B & \xrightarrow{\eta \circ u} & \mathfrak{O}_E / aI \\ u^\eta \downarrow & & \downarrow \\ \mathfrak{O}_E & \longrightarrow & \mathfrak{O}_E / I. \end{array}$$

It suffices now to show that this map is injective.

To see what the kernel I' of the composition

$$\mathfrak{O}_L \xrightarrow{\eta} \mathfrak{O}_E/aI \xrightarrow{\text{canon.}} \mathfrak{O}_E/I$$

is, let K' be the maximum unramified extension of K contained in L . Then there exists a unique K -embedding $K' \hookrightarrow E$ for which η is an \mathfrak{O}_K -algebra homomorphism, because $\mathfrak{O}_{K'}$ is formally étale over \mathfrak{O}_K . Let α be a prime element of \mathfrak{O}_L and let P be the monic minimal polynomial of α over $\mathfrak{O}_{K'}$. Since L/K' is totally ramified, P is an Eisenstein polynomial;

$$P(X) = a_0 + a_1X + \cdots + a_{n-1}X^{n-1} + X^n,$$

with $a_i \in \mathfrak{O}_{K'}$, $v_K(a_i) \geq 1$, $v_K(a_0) = 1$, and $n = e_{L/K} = [L : K']$. If β is an element of \mathfrak{O}_E with $\beta(\text{mod. } aI) = \eta(\alpha)$, we must have $P(\beta) \in aI$. Comparing the valuations of $P(\beta)$ and its terms, we see $v_K(\beta) = v_K(\alpha) = 1/n$. Thus the kernel I' is $\{x \in \mathfrak{O}_L; v_K(x) \geq m - v_K(a)\}$, which satisfies the assumption of Part (i).

If $u, v \in J(L)$ and $u^\eta = v^\eta$, we have $\eta \circ u \equiv \eta \circ v \pmod{I}$ and $u \equiv v \pmod{I'}$, from which we obtain $u = v$ by Part (b) of (i). Thus L/K has the property (P_m) .

By Proposition (3.1),(2),(ii), we have $m > u_{L/K} - e_{L/K}^{-1}$ if $m > v_K(a) + \varepsilon$. Hence $u_{L/K} \leq v_K(a) + \varepsilon + e_{L/K}^{-1}$.

If $e_{L/K}$ is prime to p , L/K is tamely ramified and

$$u_{L/K} = 1 \leq v_K(a) + \varepsilon.$$

Suppose p divides $e_{L/K}$, and let $G := \text{Gal}(L/K)$. Then $e_{L/K}u_{L/K}$ is an integer divisible by p , because $u_{L/K} = \int_0^{i_{L/K}} (G_{(x)} : 1) dx$, $p \mid (G_{(x)} : 1)$ if $x \leq i_{L/K}$, and $G_{(x)}$ may "jump" only at points $x \in e_{L/K}^{-1}\mathbb{Z}$. Hence the inequality

$$(p-1)e_{L/K}u_{L/K} \leq (p-1)e_{L/K}v_K(a) + e_{L/K}(p-1)\varepsilon + (p-1),$$

where the terms except $(p-1)$ are integers divisible by p , implies $u_{L/K} \leq v_K(a) + \varepsilon$.

COROLLARY (3.3). *Let the notation and hypothesis be as in Proposition (3.2), and let $\mathfrak{D}_{L/K}$ be the different of the extension L/K . Then we have $v_K(\mathfrak{D}_{L/K}) < v_K(a) + \frac{1}{p-1}\min\{v_K(a), v_K(p)\}$ unless $v_K(\mathfrak{D}_{L/K}) = 0$.*

Proof. If L/K is unramified, then $v_K(\mathfrak{D}_{L/K}) = 0$. If not, we have $i_{L/K} > 0$ and (Proposition (3.1),(1))

$$v_K(\mathfrak{D}_{L/K}) = u_{L/K} - i_{L/K} < u_{L/K} \leq v_K(a) + \frac{1}{p-1}\min\{v_K(a), v_K(p)\}.$$

THEOREM (3.4). *Let A be a complete discrete valuation ring with finite residue field, and fix a prime element π of A . Let K be a local field of "mixed characteristic" over A , i.e., a complete discrete valuation field K with perfect residue field which is endowed with an injective ring homomorphism $A \rightarrow K$ inducing a local homomorphism $A \rightarrow \mathcal{O}_K$. Let $n \geq 1$ be an integer and J a finite flat π -module scheme over \mathcal{O}_K ([7], §1) such that the invariant differential module ω_J of J is a free $(\mathcal{O}_K/\pi^n \mathcal{O}_K)$ -module. (A typical example of such a π -module is the kernel of π^n on a π -divisible group (loc. cit.)). Let $u_o := nv_K(\pi) + \frac{1}{p-1} \min\{nv_K(\pi), v_K(p)\}$, H the kernel of the action of $G = \text{Gal}(K^{sep}/K)$ on $J(K^{sep})$, $L := (K^{sep})^H$, and $\mathcal{D}_{L/K}$ the different of the extension L/K . Then we have $G^{(u)} \subset H$ for all $u > u_o$, and $v_K(\mathcal{D}_{L/K}) < u_o$.*

Proof. Replacing K by its maximum unramified extension, we may suppose the residue field k of K is algebraically closed. Then the general theory of group schemes says that the affine ring B of J is locally of complete intersection. Since $\Omega_{B/\mathcal{O}_K}^1 = B \otimes_{\mathcal{O}_K} \omega_J$ is a free $(B/\pi^n B)$ -module, we can apply Proposition (3.2) and Corollary (3.3) with $a = \pi^n$ and obtain the theorem.

Remark (3.5). In some simple cases, direct calculations yield sharper results. For example, let A and π be as above, F the fraction field of A , and F_n , $n \geq 0$, the field of π^n -division points of a Lubin-Tate group over A associated with π . If $L/K = F_m/F_n$ with $m > n$, we have

$$u_{L/K} = \begin{cases} m, & \text{if } n = 0 \\ q^n + (m - n - 1)q^{n-1}(q - 1), & \text{if } n \geq 1 \end{cases}$$

$$v_K(\mathcal{D}_{L/K}) = [L : K] [\min\{m, v_F(q) + q^{1-m}\} - q^{n-m+1}/(q - 1)].$$
